Exercises:

Complete the following exercise. **It is recommended to complete them in the given order**.

If you do not complete the exercises during the tutorial time, complete them at home. If you have questions, please ask them during the tutorial, by sending an email to your tutor, or at the beginning of the next tutorial.

1. Try to create the pizza database. The script for this database is stored in the file named pizza.txt. Remember to reset your terminal first (so that you do not keep previously created tables from other databases).
2. With the tables in the pizza database, try to extract all the rows from all the tables (one by one). To find out the names of the tables you can inspect the script in pizza.txt or use the command \dt
3. Now try to output all the rows of the table menu but only displaying the column pizza.
4. Now try to display the following outputs:
    a. All the pizza with price over $7.5 (the output should be: stagiony, special and seafood)
    b. All the ingredients of type fish (the output should be: anchovies, prawn, seafood)
    c. All the ingredients used in a pizza recipe with an amount over a 100g (the output should be: cheese, ham, cabanossi, salami, seafood)
5. Complete the exercises 4 to 9 (on page 2) from the Pizza database exercises file on Canvas

Note: If you need further assistance on how to create WHERE clauses using Boolean operators and LIKE, review the information in T1 (Addendum) - Like operator and Boolean Algebra
